Dense Nutrient Food

AMERICAN Scientist

From pilfered-from-predators to processed-and-packaged, animals have been part of human diets for more than 3 million years. Cooking was unquestionably a revolution in our dietary history. Cooking makes food both physically and chemically easier to chew and digest, enabling the extraction of more energy from the same amount of food. The biggest increase in brain size in our evolutionary history happened right after we see the earliest evidence for cooking.

Associations between Periodontal Microbiota and Death Rates

Chung-Jung Chiu 🏁, Min-Lee Chang & Allen Taylor

 These data suggested that specific combinations of periodontal bacteria, <u>even</u> <u>without inducing clinically significant periodontitis, may have a significant</u> <u>impact on human cause-specific death rates</u>. Our findings implied that increased disease and mortality risk could be transmittable via the transfer of oral microbiota, and that developing personalized strategies and maintaining healthy oral microbiota beyond protection against periodontitis would be important to manage the risk.

Pediatric Oral Health and Adult CVD An Just have everyone Ap Pirk USE an ant anicrobial mouth rinse??? risk factor for adult cardiovascular disease.

Nitrate reducers and exercise

Free Radical Biology and Medicine Volume 143, 1 November 2019, Pages 252-259

Original article

Post-exercise hypotension and skeletal muscle oxygenation is regulated by nitrate-reducing activity of oral bacteria

C. Cutler^a, M. Kiernan^b, J.R. Willis^c, L. Gallardo-Alfaro^d, P. Casas-Agustench^a, D. White^a, M. Hickson^a, T. Gabaldon^{c, e, f}, R. Bescos^a & 🛤

 The SBP-lowering effect of exercise was attenuated by 61% at 1 h in the recovery period, and it was fully attenuated 2 h after exercise with antibacterial mouthwash. <u>This was associated with a lack of</u> <u>changes in circulatory nitrite (P > 0.05)</u>, and impaired microvascular response <u>These findings show that nitrite synthesis by oral</u> <u>commensal bacteria is a key mechanism to induce the vascular</u> <u>response to exercise</u> over the first period of recovery thereby promoting lower blood pressure and greater muscle oxygenation.

Nitrate reducers and vegans

anion. Dietary nitrate is reduced to nitrite by commensal bacteria in the mouth, which in turn leads to increased circulatory nitrite availability. Nitrite can form nitric oxide by several pathways promoting a reduction in the vascular tone and lower blood pressure.

The 14 candidate species detected through WGS sequencing and analysis of one Nitrate representative sample from each group are listed.

Dental calculus preserves DNA of oral microbiome...

Dental Calculus- Foss

Figure 1. Supra-gingival dental calculus is identifiable in a concave ring on a lower molar from a Medieval specimen, York, UK.

Dental Calculus- Fossils

• Calcified dental plaque (dental calculus) preserves for millennia and entraps biomolecules from all domains of life and viruses. We characterize (i) the ancient oral microbiome in a diseased state, (ii) 40 opportunistic pathogens, (iii) ancient humanassociated putative antibiotic resistance genes, (iv) a genome reconstruction of the periodontal pathogen Tannerella forsythia, (v) 239 bacterial and 43 human proteins, allowing confirmation of a long-term association between host immune factors, 'red complex' pathogens and periodontal disease, and (vi) DNA sequences matching dietary sources.

Cellulose and Xylan Hydrolysis

Impact of diet in shaping gut microbiota revealed by a comparative study in children from Europe and rural Africa

Carlotta De Filippo^a, Duccio Cavalieri^a, Monica Di Paola^b, Matteo Ramazzotti^c, Jean Baptiste Poullet^d, Sebastien Massart^d, Silvia Collini^b, Giuseppe Pieraccini^e, and Paolo Lionetti^{b, 1}

 Compared the fecal microbiota of <u>European children</u> (EU) and that of children from a rural African village of Burking Faso (BF), where the diet, high in fiber content, is similar to that of early human settlements at the time of the birth of agriculture. By using high-throughput 16S rDNA sequencing and biochemical analyses, we found significant differences in gut microbiota between the two groups.

Cellulose and Xylan Hydrolysis

Impact of diet in shaping gut microbiota revealed by a comparative study in children from Europe and rural Africa

Carlotta De Filippo^a, Duccio Cavalieri^a, Monica Di Paola^b, Matteo Ramazzotti^c, Jean Baptiste Poullet^d, Sebastien Massart^d, Silvia Collini^b, Giuseppe Pieraccini^e, and Paolo Lionetti^{b, 1}

 BF children showed a significant enrichment in Bacteroidetes and depletion in Firmicutes (P < 0.001), with a unique abundance of bacteria from the genus **Prevotella and Xylanibacter**, known to contain a set of bacterial genes for cellulose and xylan hydrolysis, completely lacking in the EU children.

Life in a rural village of Burkina Faso.

Carlotta De Filippo^a, Duccio Cavalieri^a, Monica Di Paola^b, Matteo Ramazzotti^c, Jean Baptiste Poullet^d, Sebastien Massart^d, Silvia Collini^b, Giuseppe Pieraccini^e, and Paolo Lionetti^{b,1}

The SCFA-producing bacteria that are abundant in the BF children's gut possibly help to prevent the establishment of some potentially pathogenic intestinal microbes causing diarrhea, as seen by the fact that Enterobacteriaceae, such as Shigella and Escherichia, were significantly underrepresented in BF than in EU children. Increased gut microbial diversity and reduced quantities of potentially pathogenic strains in BF would agree with the "old friend" hypothesis, indicating a role of microbiota in protecting children from pathogens as well as from gastrointestinal diseases.

No guts, No glory! GUT

BMJ Journa

Gut

The microbiome of professional athletes differs from that of more sedentary subjects in composition and particularly at the functional metabolic level

• Athletes had relative increases in pathways (eg, amino acid and antibiotic biosynthesis and carbohydrate metabolism) and faecal metabolites (eg, microbial produced short-chain fatty acids (SCFAs) acetate, propionate and butyrate) associated with enhanced muscle turnover (fitness) and overall health when compared with control groups. Differences in faecal microbiota between athletes and sedentary controls show even greater separation at the metagenomic and metabolomic than at compositional levels and provide added insight into the dietexercise-gut microbiota paradigm.

We characterized a unique placental microbiome niche, composed of nonpathogenic commensal microbiota from the Firmicutes, Tenericutes, Proteobacteria, Bacteroidetes, and Fusobacteria phyla. In aggregate, the placental microbiome profiles were most akin (Bray-Curtis dissimilarity <0.3) to the human oral microbiome. 16S-based operational taxonomic unit analyses revealed associations of the placental microbiome with a remote history of antenatal infection (permutational multivariate analysis of variance, P = 0.006), such as urinary tract infection in the first trimester, as well as with preterm birth <37 weeks (P = 0.001).

Fig. 1. The placental microbiome has a taxonomic profile that is similar to the oral microbiome.

Fig. 2. Comparison of WGS-generated taxa and metabolic capacity among body sites reveals <u>distinct features of the placental microbiome</u>.

Identical mitochondrial somatic mutations unique to chronic periodontitis and coronary artery disease

Tokala Pallavi, Rampalli Viswa Chandra, [...], and Anumala Naveen

Among the complete mtDNA sequences, a total of 162 variations were spread across the whole mitochondrial genome and present only in the coronary artery and the gingival tissue samples but not in the blood samples. Among the 162 variations, <u>12 were novel and four of the 12 novel variations</u> were found in mitochondrial NADH dehydrogenase subunit 5 complex | gene (33.3%).

Viome- transcriptomics

Entire gut or oral microbiome

The term can be applied to the total set of transcripts in a given organism, or to the specific subset of transcripts present in a particular cell type. Unlike the genome, which is roughly fixed for a given cell line (excluding mutations), the transcriptome can vary with external environmental conditions. Because it includes all mRNA transcripts in the cell, the transcriptome reflects the genes that are being actively expressed at any given time, with the exception of mRNA degradation phenomena such as transcriptional attenuation.

Prevention: Prebiotics

Probiotics – great interest in research

The number of published studies investigating probiotics has increased 15 fold in as many years, and 2011 looks set to be a record year with more than 1300 publications anticipated.

An analysis of publications posted to the NIH PubMed database reveals strong growth in the number of publications featuring the keyword 'probiotic'. In 1997 there were roughly 80 publications globally per year referencing probiotics, today that figure is over 1200 per year or 100 publications per month.

Complementation of the fadA mutation in Fusobacterium nucleatum demonstrates that the surface-exposed adhesin promotes cellular invasion and placental colonization.

Ikegami A¹, Chung P, Han YW.

Author information

Promotes cell invasion and colonization

Abstract

Fusobacterium nucleatum is a gram-negative oral anaerobe implicated in periodontal disease and adverse pregnancy outcome. The organism colonizes the mouse placenta, causing localized infection and inflammation. The mechanism of placental colonization has not been elucidated. Previous studies identified a novel adhesin from F. nucleatum, FadA, as being involved in the attachment and invasion of host cells. The fadA deletion mutant F. nucleatum 12230 US1 was defective in host cell attachment and invasion in vitro, but it also exhibited pleiotropic effects with altered cell morphology and growth rate. In this study, a fadA-complementing clone, F. nucleatum 12230 USF81, was constructed. The expression of FadA on USF81 was confirmed by Western blotting and immunofluorescent labeling. USF81 restored host cell attachment and invasion activities. The ability of F. nucleatum 12230, US1, and USF81 to colonize the mouse placenta was examined. US1 was severely defective in placental colonization compared to the wild type and USF81. Thus, FadA plays an important role in F. nucleatum colonization in vivo. These results also represent the first complementation studies for F. nucleatum. FadA may be a therapeutic target for preventing F. nucleatum colonization of the host.

Fusobacterium nucleatum Promotes Colorectal Carcinogenesis by Modulating E-Cadherin/β-Catenin Signaling via its FadA Adhesin

Mara Roxana Rubinstein⁷, Xiaowei Wang⁷, Wendy Liu, Yujun Hao, Guifang Cai, Yiping W. Han 🔤

Summary

Fusobacterium nucleatum (Fn) has been associated with colorectal cancer (CRC), but causality and underlying mechanisms remain to be established. We demonstrate that *Fn* adheres to, invades, and induces oncogenic and inflammatory responses to stimulate growth of CRC cells through its unique FadA adhesin. FadA binds to E-cadherin, activates β-catenin signaling, and differentially regulates the inflammatory and oncogenic responses. The FadA-binding site on E-cadherin is mapped to an 11-amino-acid region. A synthetic peptide derived from this region of E-cadherin abolishes FadA-induced CRC cell growth and oncogenic and inflammatory responses. The *fadA* gene levels in the colon tissue from patients with adenomas and adenocarcinomas are >10–100 times higher compared to normal individuals. The increased FadA expression in CRC correlates with increased expression of oncogenic and inflammatory genes. This study unveils a mechanism by which *Fn* can drive CRC and identifies FadA as a potential diagnostic and therapeutic target for CRC.

Influence of maternal xylitol consumption on acquisition of mutans streptococci by infants.

Söderling E, Isokangas P, Pienihäkkinen K, Tenovuo J. Institute of Dentistry, University of Turku, Finland. eva.soderling@utu.fi

Abstract

Xylitol is effective as a non-cariogenic sugar substitute. Habitual xylitol consumption appears to select for mutans streptococci (MS) with impaired adhesion properties, i.e., they shed easily to saliva from plaque. One hundred sixty-nine mother-child pairs participated in a two-year study exploring whether the mothers' xylitol consumption could be used to prevent mother-child transmission of mutans streptococci. All mothers showed high salivary levels of mutans streptococci during pregnancy. The mothers in the xylitol group (n = 106) were requested to chew xylitol-sweetened gum (65% w/w) at least 2 or 3 times a day, starting three months after delivery. In the two control groups, the mothers received either chlorhexidine (n = 30) or fluoride (n = 33) varnish treatments at 6, 12, and 18 months after delivery. The children did not chew gum or receive varnish treatments. MS were assessed from the mothers' saliva at half-year intervals and from the children's plaque at the one- and two-year examinations. The MS were cultured on Mitis salivarius agars containing bacitracin. The salivary MS levels of the mothers remained high and not significantly different among the three study groups throughout the study. At two years of age, 9.7% of the children in the xylitol, 28 6% in the chlorhexidine, and 48.5% in the fluoride varnish group showed a detectable level of MS. In conclusion, therefore, habitual xylitol consumption by mothers was associated with a statistically significant reduction of the probability of mother-child transmission of MS assessed at two years of age. The effect was superior to that obtained with either chlorhexidine or fluoride varnish treatments performed as single applications at six-month intervals.

Effectiveness of CRT at Measuring the Salivary Level of Bacteria in **Caries Prone Children with Probiotic Therapy**

Cannon M* / Trent B** / Vorachek A*** / Kramer S**** / Esterly R*****

Aim: This IRB approved clinical trial was to determine the effect of "over the counter" probiotic supplements on the Caries Risk Test- CRT- (Ivoclar) results of the oral microflora in high caries risk children. Study design: Sixty subjects 6 to 12 years old with a caries risk assessment (CAMBRA) of moderate to high (caries prone) were evaluated by an analysis of the difference in the salivary levels of pathogenic bacteria (mutans streptococci and Lactobacilli). The subjects were randomly selected by randomizing software and assigned to two different Groups, Group A used PerioBalance (Lactobacilli reuteri-CFU of 200 million) lozenges for 28 days, Group B used the EvoraKids (Streptococcus uberis KJ2, Streptococcus oralis KJ3, Streptococcus ratius JH145, ≥ 100 million) probiotics chewable tablets for 30 days. Salteary samples were collected then incubated for 48 hours for colony counting and ranking. Follow up testing with the CRT was performed after 60 days at a follow up visit. Results: There was a statistically significant difference in the CRT results between the pre-and post use of the probiotics. PerioBalance; SM results t= -6.78 p< .0001 Lactobacilli results t= -5.762, p< .0001, EvoraKids SM results t= -7.33, p< .0001, Lactobacilli results t= -2.952, p= .0068. Conclusions: The CRT values obtained with caries prone children may be significantly affected by probiotic use. Based on this study's results the following conclusions can be made: Both EvoraKids and PerioBalance affected the CRT results by significantly decreasing the number of S. mutaus and lactobacilli present in the salivary samples.

An IRB Approved Study

Does EvoraKids and PerioBalance affected the caries proneness of the subjects? Is the reduction in *dental* caries was statistically significant?

Children's Memorial Hospital Where kids come first.

Materials and Methods:

Dental records of 60 patients that were enrolled in the Institutional Review **Board approved study, "A clinical trial** to evaluate the effectiveness of DNA-**PCR and CRT at measuring the salivary** level of bacteria in caries prone children with PerioBalance or **EvoraKids Plus therapy" were reviewed** as to current caries activity status with measurement of the Decay Missing **Filled Teeth index and Caries By Risk Assessment (CAMBRA) determination.** The current Oral health status was compared to the prior-to-study enrollment status and then analyzed in respect to published national norms.

<u>Results:</u>

Of the **53 subjects** available for follow up, only 4 had remained caries active with a grand total of 17 caries lesions being detected and subsequently restored in this group. Of the original total of 60 patients with 292 initial carious lesions, after probiotic therapy and dental restoration, 36 total restorations were place in the subject group over the following three years. Approximately half of these restorations were required in teeth that had initially presented with smaller lesions and had been placed in a "watch" category. Two of the patients that developed further carious lesions had been randomly assigned to the probiotic PerioBalance, what the other two caries active patients were assigned EvoraKids probiotic.

Of the original group of caries active patients, 23 did not present with any further carious involvement. Another 26 could be categorized as Caries static, as the restorations required were substantially less than before probiotic therapy had been begun.

Further Research

Conclusion: Within the limitations of this retrospective **IRB** approved study, the tested probiotic supplements had a statistically significant effect on the caries experience of the enrolled subjects.

AUISM Spectrum Disorder

CDC estimate of autism prevalence increases to 15%. Now 1 in 59 children.

Autism Speaks calls on nations' leaders to adequately fund critical research and resources

NEW YORK (April 26, 2018) The Centers for Disease Control and Prevention (CDC) today released its biennial update of autism's estimated prevalence among the nation's children, based on an analysis of 2014 medical and/or school records of 8-year-olds from 11 monitoring sites across the United States. The report demonstrates that while progress has been made on some fronts, there is still critical work to do.

Gut bacteria in children with autism spectrum disorders: challenges and promise of studying how a complex community influences a complex disease

Rosa Krajmalnik-Brown, 1.2.* Catherine Lozupone, 3 Dae-Wook Kang, 1 and James B. Adams4

Prevotella, is highly enriched in the fecal microbiota in populations in Africa including agrarian societies in Malawi and Burkina Faso, and the Hadza hunter-gatherers in Tanzania intrigued us and inspired us to perform comparative analyses. Since Prevotella is only one genus in the very diverse gut microbiota and has a tendency to co-occur with a complex collection of other bacteria species, we wanted to determine whether **Prevotella depletion in** children with ASD is an indicator that the gut microbiome of children with ASD who live in the United States differs even more from individuals in the developing world than does the gut microbiome of neurotypical children in the US, providing evidence of the gut microbiota as an environmental factor that may correlate with increased rates of ASD in industrialized countries.

Table 1. Evidence for the link between Clostridium bacteria and autism spectrum conditions. Table summarizing the main results of nine studies included in the systematic review. The table is organized by year of publication.

TITLE	AUTHOR / YEAR	PMID	MATERIAL	Nº PATIENTS / CONTROLS	CONCLUSIONS
Gastrointestinal microflora studies in late-onset autism	Finegold et al., 2002	12173102	Human (Stools)	13 ASD / 8 controls	Children with autism had nine species of Clostridium not found in controls, with significant alterations in the upper and lower intestinal flora of children with late-onset autism
Real-time PCR quantitation of clostridia in feces of autistic children	Song et al., 2004	15528506	Human (Stools)	15 ASD / 8 controls	Analysis of the real-time PCR data showed cell count differences between autistic and control children for Clostridium boltene
Differences between the gut microflora of children with autistic spectrum disorders and that of healthy children	Parracho et al., 2005	16157555	Human (Stools)	58 ASD / 22 controls (2 groups)	The fecal flora of autism spectrum disorder (ASD) patients contained a higher incidence of the <i>Clostridium histolytician</i> group (Clostridium clusters I and II) of bacteria than that of healthy children
Fecal lactoferrin and Clostridium spp. in stools of autistic children	Martirosian et al., 2011	21167951	Human (Stools)	41 ASD / 10 controls	Elevated level of fecal lactoferrin was demonstrated in 24.4% stools, all from boys (31.25%). No toxins were detected. <i>Clostridium spp.</i> was isolated with similar frequency from all samples. <i>Clostridium</i> <i>perfrincens</i> were isolated significantly often from the autistic stools
Fecal microbiota and metabolome of children with autism and pervasive developmental disorder not otherwise specified	De Angelis et al., 2013	24130822	Human (Stools)	20 ASD / 10 controls	The highest microbial diversity was found in ASD children. Based on 16S-rRNA and culture-dependent data, Faecalibacterium and Ruminococcus were present at the highest level in fecal samples of pervasive developmental disorder not otherwise specified (PDD- NOS) and healthy children. Caloramator, Sarcina and Clostridium genera were the highest in ASD children
Urinary 3-(3-Hydroxyphenyl)-3- hydroxypropionic Acid, 3- Hydroxyphenylacetic Acid, and 3- Hydroxyhippuric Acid Are Elevated in Children with Autism Spectrum Disorders	Xiong et al., 2016	27123458	Human (Urine)	62 ASD / 62 controls	Measurement of these three compounds (aromatic metabolites in autism patients are presumably derived from overgrown Clostridium species in gut) are strong predictors of ASDs and support the potential clinical utility for identifying a subgroup of ASD subjects
Intestinal Dysbiosis and Yeast Isolation in Stool of Subjects with Autism Spectrum Disorders	Iovene et al., 2017	27655151	Human (Stools)	47 ASD / 33 controls	Significant linear correlation was found between disease severity and calprotectin and <i>Clostridium spp.</i> presence in the stool of subjects with ASD
Analysis of the Duodenal Microbiome in Autistic Individuals: Association with Carbohydrate Digestion	Kushak et al., 2017	27811623	Human (Intestinal biopsies)	21 ASD / 19 controls	A positive correlation was found between the abundance of Clostridium species and disaccharidase activity in autistic individuals
Detection of <i>Clostridium perfringens</i> toxin genes in the gut microbiota of autistic children	Finegold et al., 2017	28215985	Human (Stools)	33 ASD / 13 controls	The author's results indicate that autistic subjects with gastrointestinal disease harbor statistically significantly higher counts of C. perfringens and β2-toxin gene-producing C. perfringens in their gut when compared to control children. In addition, the incidence of β2-toxin gene-producing C. perfringens is also significantly higher in these autistic subjects

CDC puts C difficile burden at 453,000 cases, 29,000 deaths

Filed Under: Antimicrobial Resistance; Clostridium difficile Robert Roos | News Editor | CIDRAP News | Feb 25, 2015

On the basis of a 2011 study, the Centers for Disease Control and Prevention (CDC) has increased its estimate of the annual burden of *Clostridium difficile* infections in the United States, putting it at 453,000 cases per year, with 29,300 associated deaths.

The agency, which released the findings in the New England Journal of Medicine (NEJM), said they point up the need for better antibiotic stewardship and rigorous infection control in healthcare facilities.

C diff infections occur when someone is exposed to the pathogen while receiving antibiotic treatment for some other illness. Antibiotics suppress the normal bacteria in the colon, allowing *C diff* to flourish,

bacteria in the colon, allowing *C diff* to flourish, producing toxins that cause severe diarrhea. Damage to the colon can cause bacteria to leak into the bloodstream.

The CDC found that about two thirds of the 453,000 cases were related to a stay in a hospital or nursing home and the other third were community-associated cases, involving people with no recent hospital or nursing home exposure. Most of those who died were elderly.

epigenetic dysregulation.

CONCLUSION: Data reviewed in this article highlight a variety of situations in which epigenetic dysregulation is associated with the development of ASD, thereby supporting a role for epigenetics in the multifactorial etiologies of ASD.

Methylomic analysis of mo autism spectrum disorder a

C C Y Wong¹, E L Meaburn^{1,2}, A Ronal C Schalkwyk¹, R Plomin¹ and J Mill^{1,4}

Genome-wide analysis of DNA methylation in a sample of **50 MZ twin pairs** (**100 individuals**) sampled from a representative population cohort that included twins discordant and concordant for ASD, ASD-associated traits and no autistic phenotype.

Significant correlations between <u>DNA methylation</u> and quantitatively measured autistic trait scores across our sample cohort. This study represents the first <u>systematic epigenomic</u> <u>analyses of MZ twins discordant for ASD</u> and implicates a role for altered DNA methylation in autism.

Modulation of Immunological Pathways in Autistic and Neurotypical Lymphoblastoid Cell Lines by the Enteric Microbiome Metabolite Propionic Acid

Richard E. Frye^{1,2*}, Bistra Nankova³, Sudeepa Bhattacharyya^{1,2}, Shannon Rose^{1,2}, Sirish C. Bennuri^{1,2} and Derrick F. MacFabe⁴

Propionic acid (PPA) is a ubiquitous short-chain fatty acid which is a fermentation product of the enteric microbiome and present or added to many foods. PPA modulates mitochondrial dysfunction differentially in subsets of lymphoblastoid cell lines (LCLs) derived from patients with ASD. <u>Specifically, PPA significantly increases</u> <u>mitochondrial function in LCLs that have mitochondrial dysfunction at baseline</u> [individuals with autistic disorder with atypical mitochondrial function (AD-A) LCLs] as compared to ASD LCLs with normal mitochondrial function [individuals with autistic disorder with normal mitochondrial function (AD-N) LCLs] and control (CNT) LCLs.

Association Between Gut Microbiota and Autism Spectrum Disorder: A Systematic Review and Meta-Analysis

We analyzed nine studies, including 254 patients with ASD, and found that children with ASD had lower percentages of Akkermansia, Bacteroides, Bifidobacterium, and Parabacteroides and a higher percentage of Faecalibacterium in the total detected microflora compared to controls. In contrast, children with ASD had lower abundance of Enterococcus, Escherichia coli,
 Bacteroides, and Bifidobacterium and higher abundance of Lactobacillus. This meta-analysis suggests an association between ASD and alteration of microbiota composition and warrants additional prospective cohort studies to evaluate the association of bacterial changes with ASD symptoms, which would provide further evidence for the precise microbiological treatment of ASD.

Prebiotic potential of L-sorbose and xylitol in promoting the growth and metabolic activity of specific butyrate-producing bacteria in human fecal culture

Tadashi Sato 🐱, Shiro Kusuhara, Wakae Yokoi, Masahiko Ito, Kouji Miyazaki

FEMS Microbiology Ecology, Volume 93, Issue 1, 1 January 2017, fiw227, https://doi.org

Dietary low-digestible carbohydrates (LDCs) affect gut microbial metabolism, including the
production of short-chain fatty acids. Fecal suspensions from five healthy males were anaerobically
incubated with various LDCs. L-Sorbose and xylitol markedly promoted butyrate formation in
cultures. Bacterial 16S rRNA gene-based denaturing gradient gel electrophoresis analyses of
these fecal cultures revealed a marked increase in the abundance of bacteria
closely related to the species Anaerostipes hadrus or A. caccae or both,
during enhanced butyrate formation from L-sorbose or xylitol.

Gum Disease Can Kill More Than Your Smile 21 C

Bacteria that builds up between the tooth and gum can enter into the bloodstream whenever your gums bleed. This bacteria can travel throughout the body and cause serious health problems.

STROKE

A new study of fatty deposits lodged in the carotid arteries of stroke sufferers shows that up to 40% of the bacteria that cause the fatty deposits comes from the mouth if the gums are inflamed

RESPIRATORY DISEASE (ard most common cause of death) Dental plaque harbors a high number of respiratory pathogens that can be aspirated and, in turn, increase the risk in susceptible patients for pneumonia, emphysema and chronic obstructive lung disease.

HEART DISEASE

Bacteria from the mouth can get into the bloodstream when the gums are inflamed. This bacteria can get mixed up with blood-clotting cells called platelets. These clumps of cells and bacteria can lodge inside the walls of the blood vessels, causing heart-stopping clots to form. These clots are what lead to heart disease. Keeping your gums healthy can reduce your risk of a heart attack.

DIABETES (pancreas)

The presence of any gum inflammation can make it much more difficult for a diabetic to control their blood sugar. Elimination of any gum inflammation can directly improve diabetic control. A study of 48,000 men (Health Professionals Study 1986-2002) found that men who had periodontal disease had a 63% higher risk of developing pancreatic cancer than men with healthy gums.

ULCERS (stomach)

The bacteria that collect in your mouth when gum disease is present are the same bacteria that cause gastric ulcers. If the bacterial count in the mouth is high these bacteria can be constantly travelling to the stomach, reinfecting and causing a return of ulcers.

OSTEOPOROSIS

Periodontal disease may play a role in promoting osteoporosis. With tooth loss there is a decrease in proper digestion, nutrition and calcium uptake.

ARTHRITIS

There is a strong relationship between the extent and severity of periodontal disease and Rheumatoid Arthritis.

PRE-TERM BIRTHS

Women with gum disease are seven to eight times more likely to give birth prematurely to low birth weight babies. Researchers believe that the low grade gum inflammation causes the body to release inflammatory chemicals which are linked to pre-term birth.

Assessi How about antibiotics?

Oral infections with Porphyromonas gingivalis, or introduction of its lipopolysaccharide (LPS), in various mouse models has demonstrated the development of key neuropathological hallmark lesions defining AD. These are extracellular amyloid-beta plaques, phosphorylated tau, neurofibrillary tangles, widespread acute and chronic inflammation, blood-brain barrier **defects** together with the clinical phenotype showing impaired learning and spatial memory. Live P. gingivalis and its LPS (commercial or from 'microbullets') are powerful peripheral and intracerebral inflammatory signaling initiators, and this has direct implications on memory and lesion development.

Obesity and Risk for Second Malignant Neoplasms in Childhood Cancer Survivors: A Case–Control Study Utilizing the California Cancer Registry

Diana J. Moke, Ann S. Hamilton, Leena Chehab, Dennis Deapen, and David R. Freyer

Obesity is a known modifiable risk factor associated with adverse outcomes in children with cancer. We sought to determine whether obesity during childhood cancer treatment increases risk for second malignant neoplasms (SMN). There was a significantly increased risk for SMN among patients who were obese at both diagnosis and EOT [aOR, 4.44 (1.37–14.34)]. This study suggests that obesity during childhood cancer treatment may be associated with increased risk for SMNs, particularly among those obese throughout therapy.

Topical treatment with probiotic *Lactobacillus brevis* CD2 inhibits experimental periodontal inflammation and bone loss

T. Maekawa, G. Hajishengallis 💌

 Mice topically treated with L. brevis CD2 displayed <u>significantly</u> <u>decreased bone loss</u> and lower expression of tumor necrosis factor, and interleukin-1β, -6 and -17A as compared to placebo-treated mice. Moreover, L. brevis CD2-treated mice displayed lower counts of anaerobic bacteria but higher counts of aerobic bacteria than placebo-treated mice.
